A. GENERALIZED DESCRIPTION OF PETROLEUM REFINING AND THE ADL LP MODEL

## APPENDIX A

### 1. LINEAR PROGRAMMING (LP) TECHNIQUE

The simulation of refinery processing in this study has been made using the Linear Programming (LP) technique. LP is a mathematical technique which enables a large number of inter-relationships to be studied using computer technology to speed up the process of problem solving. It is a technique which is highly suitable for the study of continuous process operations such as oil refining. It is widely used by refiners to:

- o Plan refinery process capacity modifications/additions; and
- o Plan refinery operations over various timeframes.

In particular, LP modelling can be used to monitor changes in refining operations as various parameters, such as diesel aromatics and sulfur level, are changed. It can study changes in:

- o Direct fuel used for process heat (most refining processes use heat to achieve their objectives);
- o Indirect fuel for steam raising;
- o Other energy requirements (e.g., electricity);
- o Variable operating costs;
- o Existing process capacity utilization; and
- o New process capacity requirements.

The LP technique derives an "optimum" solution to each individual problem by either maximizing or minimizing any pre-determined parameter. It could therefore minimize energy, maximize revenue, minimize costs and so on. For the purposes of this study, we have used cost minimization to derive "optimum" solutions. We believe that the cost minimization approach will produce results which are consistent with the day-to-day objectives of refiners.

### 2. CATEGORIZATION OF INDUSTRY BY REFINERY GROUP

One major problem facing a study of this nature is the need to strike a balance between complexity and simplicity. On the one hand, simulation of each refinery would require an enormous work effort and conversely a single model simulation of the total refining industry would grossly underestimate the complexities of the refining situation.

In 1986, there were thirty operating refineries in California, each with a slightly different configuration. These variations lead to the use of different options to achieve more restrictive product qualities. To analyze these differences and the cost associated with them, we divided the thirty California refineries into six groups.

We obtained information about the operation of California refineries through a confidential refinery survey.

Based on the survey information, we selected the following refineries for modeling:

<u>Group</u>	<u>Description</u>	<u>Refinery/Location</u>
I	Topping	None *
II	Hydroskimming	Kern Oil-Bakersfield
III	Conversion	Unocal - Los Angeles
IV	Deep Conversion	
	- w/o hydrocracking	Shell - Wilmington
V	Deep Conversion	
	- LA Basin	ARCO - Carson
VI	Deep Conversion	
	- Northern CA	Exxon - Benicia

\* Since topping refineries generally do not produce gasoline and produce only a small volume of diesel, we chose not to model this refinery type. We estimated the costs for this refinery type outside the LP model.

We cannot provide a detailed description of the individual refinery models used in this analysis since this information is confidential. We have, however, provided a generalized description of major refinery types and a generalized description of the Arthur D. Little LP model below.

### 3. DESCRIPTION OF MAJOR REFINERY PROCESS TYPES

#### A. Process Unit Functions

Oil refineries are made up of a series of different process units. Each refinery process unit can be classified as performing one or more of the following functions:

- o separation,
- o conversion, and
- o treating.

Separation involves a physical process (not a chemical process) which divides an oil into its component parts. Distillation is the most frequent separation process used in refineries. Distillation separates components by boiling range. The first process in a refinery is generally an atmospheric distillation unit. This unit separates crude oil into such components as naphtha, kerosene, gas, oil and long residue. These components are thus available for further processing in the refinery. A simplified diagram of a crude distillation (separation) process is shown on Figure A-1. Separation processes include:

- o Atmospheric distillation,
- o Vacuum distillation,
- o Solvent extraction,
- o Mole sieve separation,
- o Cryogenic separation, and
- o Gravity separation.

Conversion processes produce a chemical change in refinery components by altering the molecular structure of the components. Fluid Catalytic Cracking (FCC) and Hydrocracking (HCC) break heavy, long chain molecules found in resid into lighter components such as gasoline and distillates. A simplified flow diagram of an FCC unit is shown on Figure A-2.

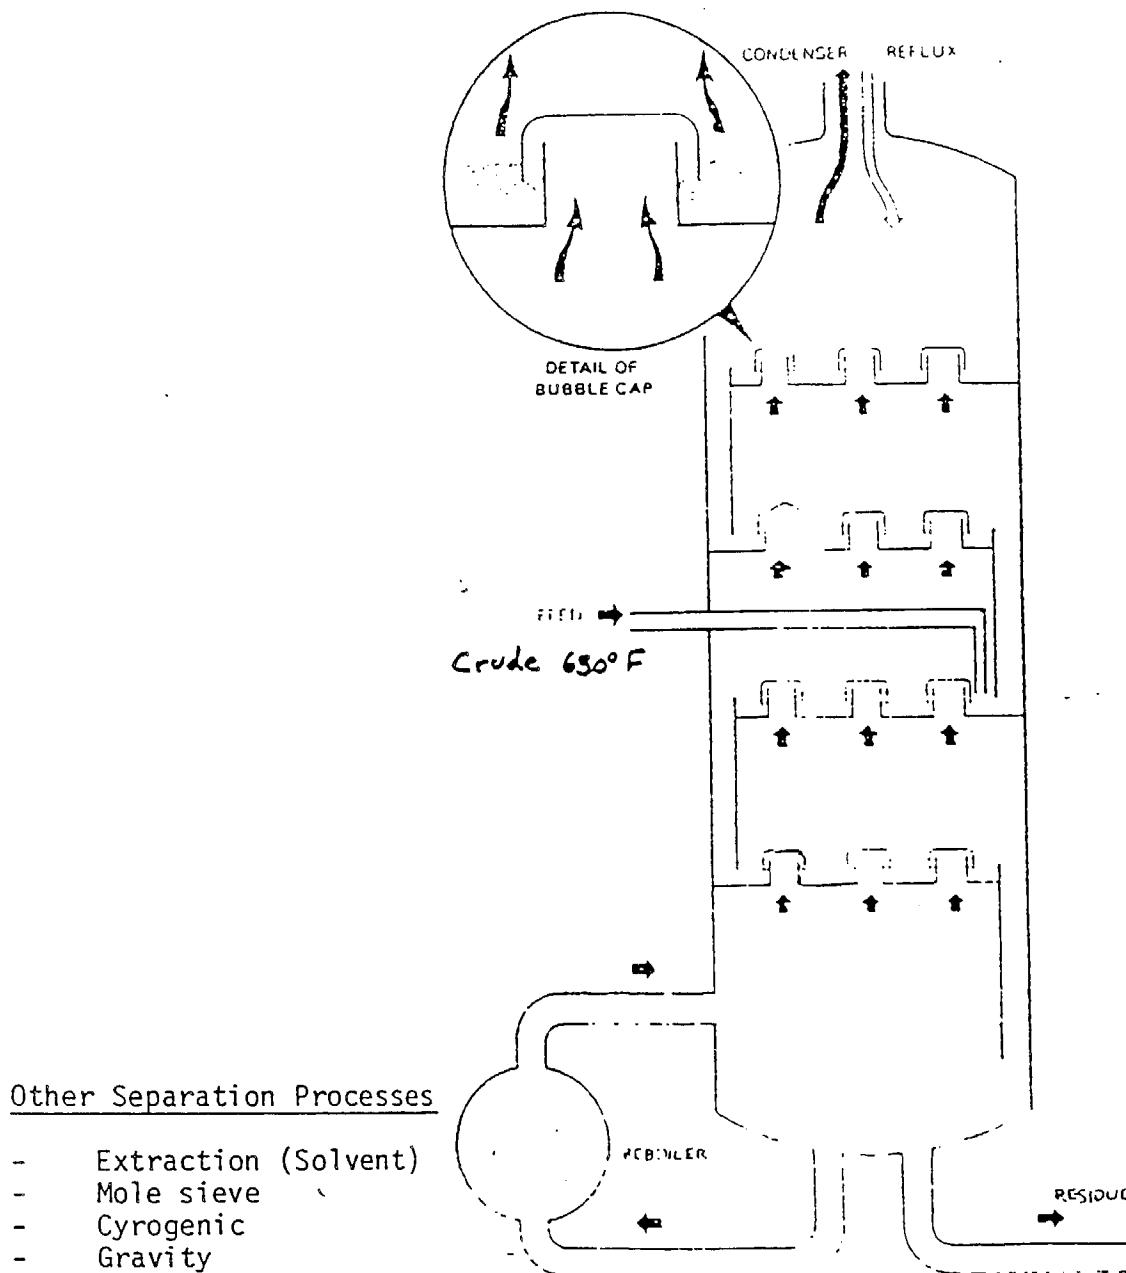

Catalytic Reforming, another type of conversion process, converts low octane naphtha into high octane gasoline blendstock. Reforming rearranges low octane naphthenes (cyclic compounds) into high octane aromatic compounds such as benzene and toluene. Conversion processes include:

- o Fluid catalytic cracking,
- o Catalytic hydrocracking,
- o Thermal cracking/visbreaking,
- o Coking,
- o Residual upgrading,
- o Alkylation,
- o Polymerization, and
- o Isomerization.

Treating units remove impurities such as sulfur and nitrogen from refinery streams. Treating can be used to improve the quality of a component prior to blending. A component stream might also be treated before it is processed in a conversion unit. This can be done to prevent catalyst poisoning and/or to improve the quality of the products produced in the conversion process. A simplified flow diagram of a catalytic hydrodesulfurization (treating) process is shown on Figure A-3. Treating processes include:

- o Hydrodesulfurization,
- o Merox treating,

 G.E. Handwerk, Marcel Dekker, 1975.

Other Treating Processes

- Merox
- Caustic
- Acid
- Clay
- Amine
- Sulfur Recovery

- o Caustic treating,
- o Acid treating,
- o Clay treating,
- o Amine extraction,
- o Sulfur recovery, and
- o Desalting.

All refinery process units are made up of combinations of the above three process types.

#### B. Refinery Configuration Types

Refineries can be divided into four configuration types based on the process units present. The four configuration types are:

- o Topping,
- o Hydroskimming,
- o Conversion, and
- o Deep conversion.

These refinery types are given in order of increasing complexity. Each successive configuration type includes the same processes as the preceding type and adds one or more additional distinguishing process. Figure A-4 provides a summary of the basic characteristics and distinguishing processes for each of these configurations.

An increase in refinery complexity enables the refinery to process the same barrel of crude oil into a greater yield of light and valuable products. A complex conversion or deep conversion refinery is able to produce gasoline and diesel at the expense of low value residual fuel. However, the greater the complexity, the higher the investment cost, maintenance cost and manpower requirements.

##### 1. Topping Refinery

The simplest refinery configuration is topping. A topping refinery uses a separation process--atmospheric distillation--to separate crude into its natural fractions: LPG and lighter, naphtha, kerosene, distillate, and long resid. A simplified process flow diagram for a typical topping refinery is shown on Figure A-5. California Group I are topping refineries.

A topping refinery consists of a crude desalter and an atmospheric distillation tower. Although not shown, a topping refinery might also have a vacuum distillation unit which further distills long resid into vacuum gas oil and short resid. Vacuum gas oil can be sold as cracker feedstock or for lube oil blending. Short resid may be sold as asphalt. Long resid (or short resid) would normally be cut (i.e., blended to meet viscosity) with distillate to produce residual fuel.

Figure A.4

Figure A.5

TYPICAL TOPPING REFINERY

Volume: 000 B/D

A topping refinery cannot directly produce gasoline since the octane quality of naphtha is quite low. In countries where significant lead (TEL) blending is allowed, a low octane gasoline product can be produced from naphtha.

## 2. Hydroskimming Refinery

Hydroskimming refineries are one step more complex than topping units. A simplified diagram for a typical hydroskimming refinery is shown in Figure A-6. The first two process units in this refinery--crude desalting and distillation unit--are identical to those in a topping refinery. The distinguishing process in a hydroskimming refinery is the catalytic reformer. California Group II are hydroskimming refineries.

A reformer is a catalytic process which upgrades naphtha into gasoline quality material. The crude naphtha must be treated in a naphtha pretreater to remove sulfur and nitrogen which would otherwise poison the reformer catalyst.

Figure A.6 also shows three other process units which may, or may not, be present in a hydroskimming refinery. These units are isomerization, distillate desulfurizing and vacuum distillation.

An isomerization unit converts the lightest naphtha fraction into gasoline quality by converting straight chain hydrocarbons into isomers (i.e., branched hydrocarbons). Isomerization units are popular in countries with lead phasedown requirements. The light straight run naphtha would be blended to gasoline even if an isom unit was not available.

The need for a distillate desulfurizing unit is set by the sulfur specification of the distillate product and the crude oil being processed. The distillate produced from sweet crudes (i.e., low sulfur) may not require desulfurization to current specifications. However, sour crudes, especially when processed in locations with stringent distillate sulfur specs, would require desulfurization.

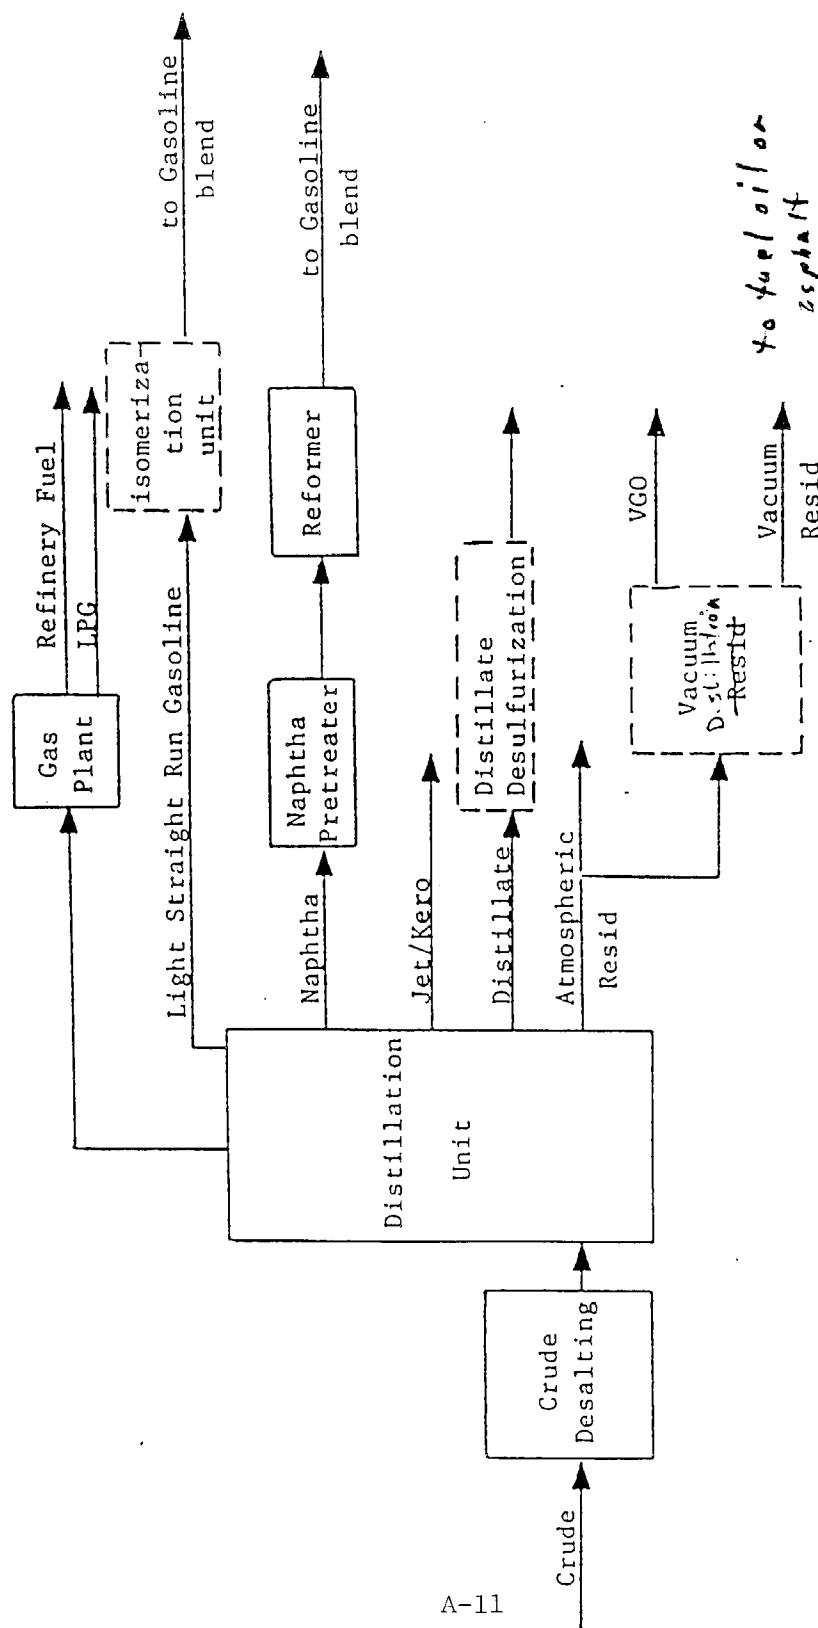

The vacuum distillation unit would be included in a refinery if the vacuum gas oil had a more profitable alternative than residual fuel blending, such as lubricating oils or feedstock to more complex (conversion) refineries. Vacuum distillation is also required to produce asphalt.

Hydroskimming refineries cannot produce more light product from a crude than is naturally available. These refineries simply have the capability of upgrading the naturally occurring naphtha in the crude to gasoline.

## 3. Conversion Refinery

A simplified process flow diagram for a typical conversion refinery is shown in Figure A-7. The processes shown outside the dashed lines are

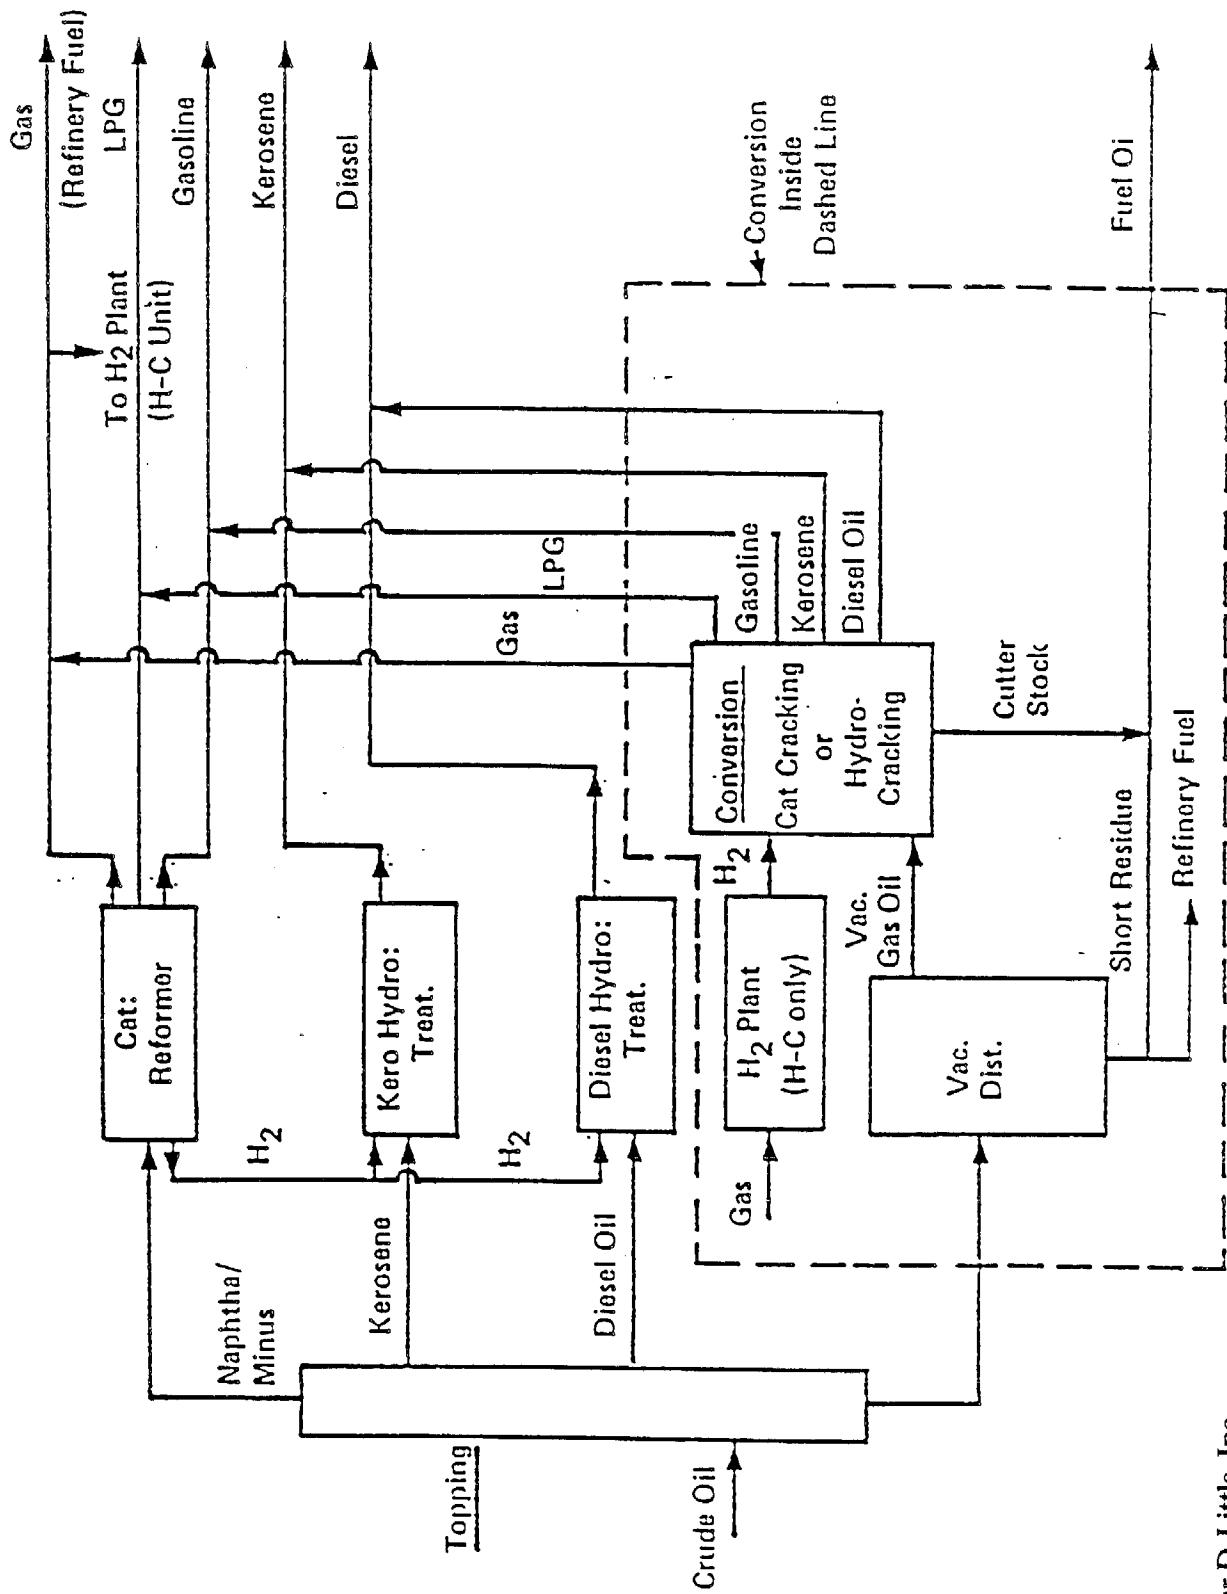

Figure A.6

HYDROSKINNING REFINERY

Figure A.7

**CONVERSION REFINERY (SIMPLIFIED)**

identical to those for a hydroskimming refinery. The distinguishing process is the conversion unit shown inside the dashed line. California Group III are conversion refineries.

The conversion process can either be an FCC unit, a hydrocracking unit, or a thermal cracking unit. In each case, the vacuum gas oil (VGO) which would otherwise go to residual fuel, is cracked into lighter products.

An FCC unit uses a fluidized catalyst at high temperatures to crack the VGO into lighter products. An FCC unit does not fully convert the feed to lighter products. The residual, or uncracked portion, is shown here as cutter stock. The sulfur in the VGO feed to an FCC unit remain in the conversion products which require further treatment for sulfur removal.

A hydrocracking (HCC) unit operates under extremely high pressure in the presence of hydrogen to upgrade all the VGO into light products. In California some cracked distillates are also generally input to the HCC to produce Jet Fuel and Gasoline. The products from an HCC unit are extremely low in sulfur and require little further treatment.

A thermal cracking unit is less severe than either of the above processes, and only converts a portion of the VGO into lighter products. As in the case of the FCC unit, the products require further treatment for sulfur removal.

In a conversion refinery, the short residue or vacuum tower bottoms is blended to fuel oil or sold as asphalt. FCC cutter stock or distillate is used with the short residue to produce an acceptable viscosity fuel.

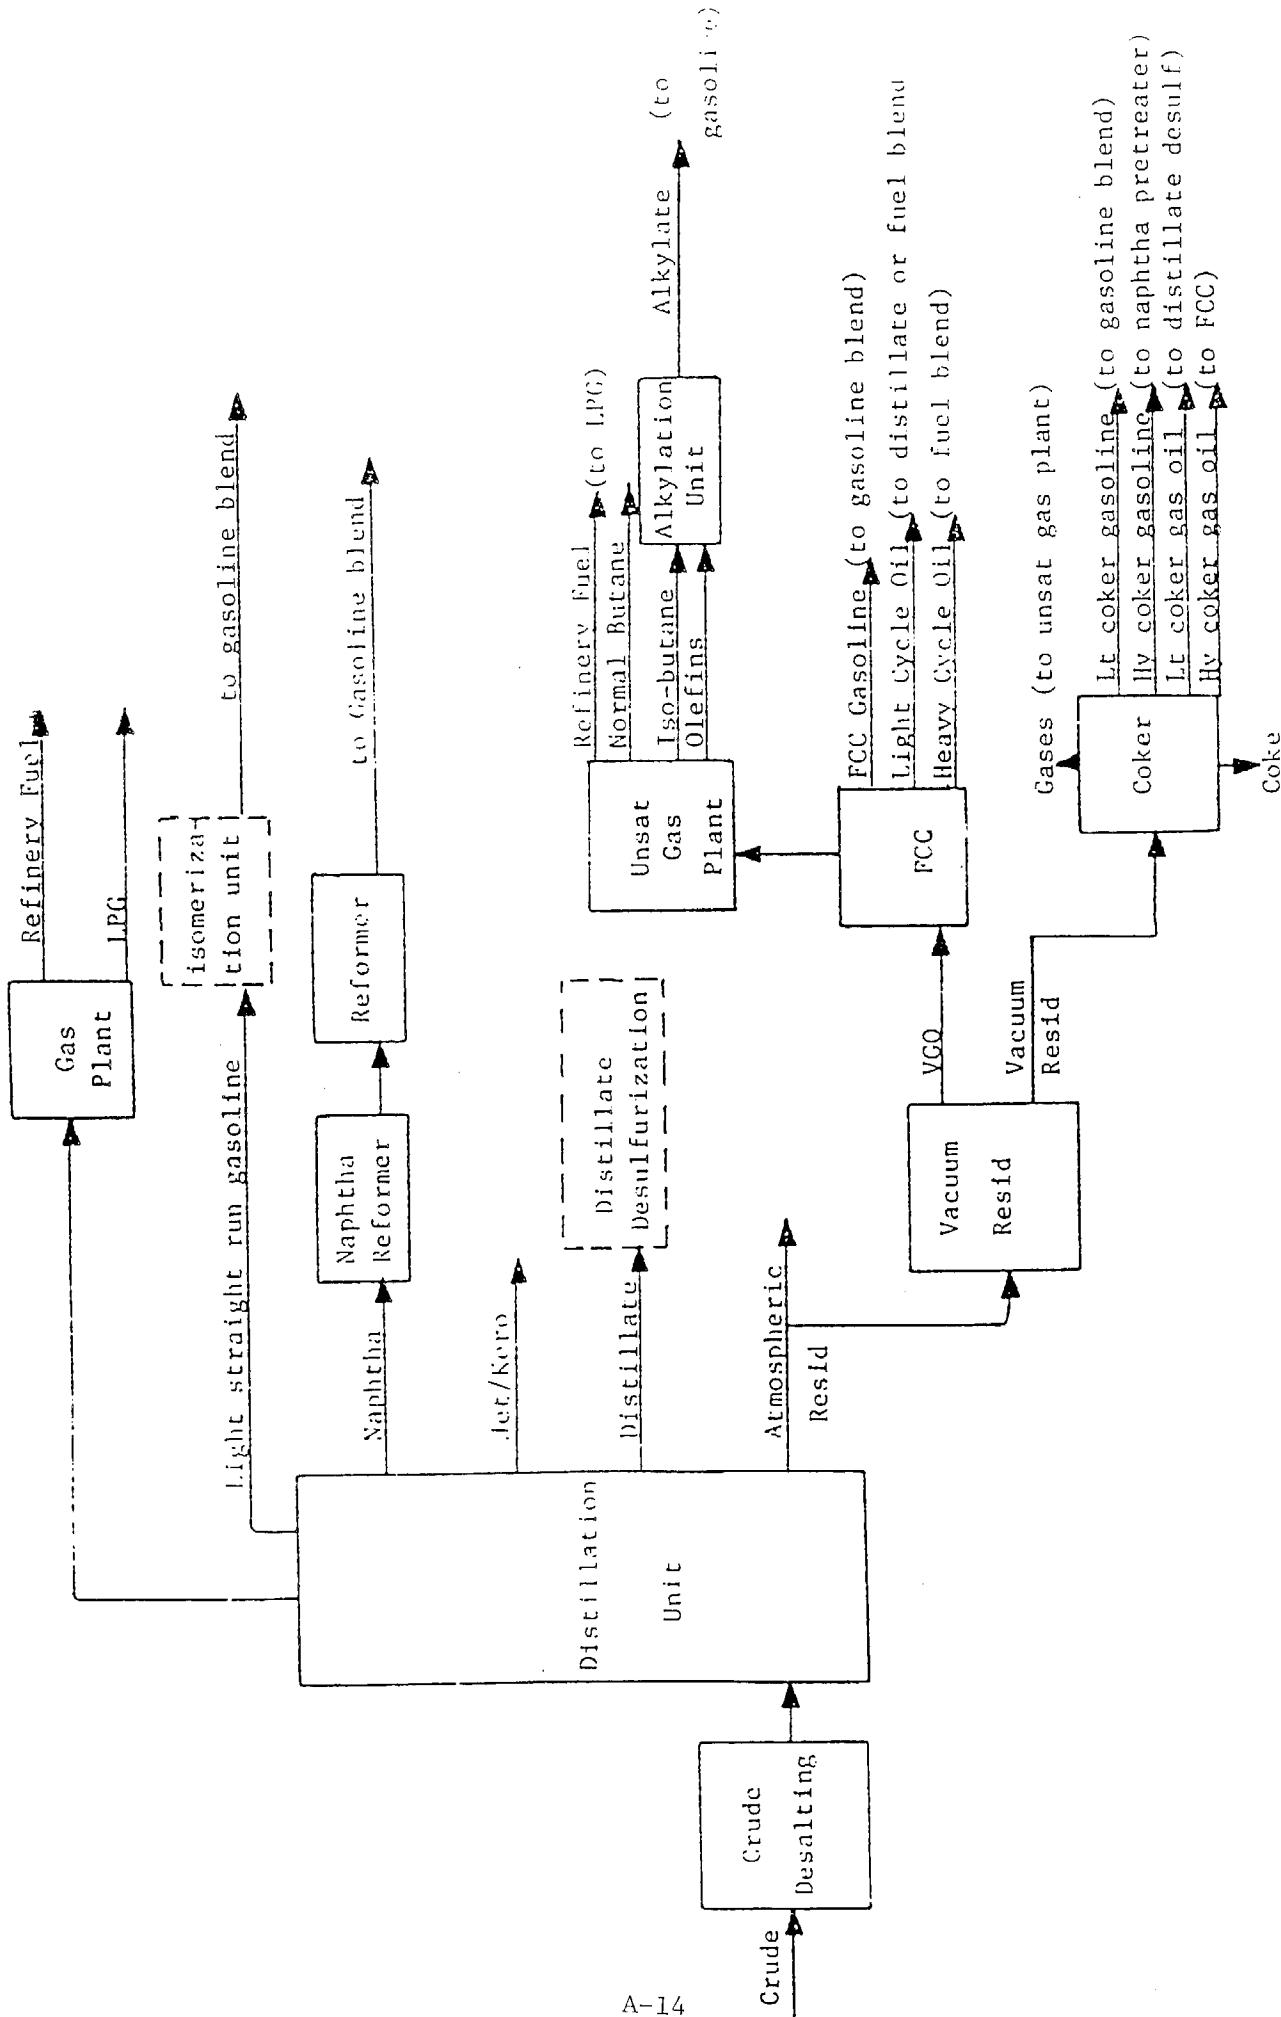

#### 4. Deep Conversion Refinery

Deep conversion is the most complex form of refinery configuration. A deep conversion refinery converts all residual fuel components into lighter, more valuable products and coke<sup>1</sup>. California Groups IV, V and VI refineries are in this category.

Figure A-8 is a simplified flow diagram for a typical deep conversion refinery. The flow diagram is the same as a conversion refinery except for the addition of the coker. In this particular drawing, the VGO conversion process is shown as an FCC unit. A hydrocracking unit could be substituted as the VGO conversion process. The alkylation unit, however, would only be suitable with an FCC since it requires light olefin (unsaturated compounds) feedstock which is produced from FCC units, but not HCC units. California Group IV refineries have only a FCC unit. California Group V and VI refineries have both a FCC operation on VGO and HCC unit operating on cracked distillates.

<sup>1</sup> Coal-like substance produced in a delayed coking process.

Figure A.8

The coker uses the heaviest portion of the crude--vacuum resid--as its feedstock. The coker produces light coker gasoline which is blended directly to gasoline. The heavy coker gasoline is treated and reformed to improve its octane. Light coker gas oil is either a distillate blendstock or can be upgraded to gasoline on an FCC unit. The heavy coker gas oil is further upgraded in either the FCC or HCC conversion process. The coker products require treating to remove sulfur.

Coking units also produce coke which is a solid, coal-like material. Coke can be used in a blend with coal in utility boilers. Coke is also used in the production of cement and to produce electrical anodes.

Deep conversion refineries do not produce a residual fuel product. Coking refineries with FCC units may sell their cutter stock (heavy cycle oil) to others who blend residual fuel.

The isomerization and distillate desulfurizing units shown in Figure 8 are optional units in any type of refinery. An isom unit would be built at a refinery short on octane. A refiner's decision to use a distillate desulfurizer is based on crude slate and distillate product specifications.

#### Summary

There are three basic refinery processes functions: separation, conversion and treating. All refinery process units combine of one or more of these basic process functions.

There are four refinery configuration types which are distinguished from one another by the process units they contain. The simplest refinery types are topping and hydroskimming which yield products at the level naturally available from the crude. Hydroskimming is distinguished from topping by its reformer which allows the refinery to produce gasoline rather than naphtha.

Conversion and deep conversion refineries convert the heavier fractions of the crude oil into lighter products. Conversion refineries upgrade the vacuum gas oil portion of the crude. Deep conversion refineries convert both the vacuum gas oil and vacuum resid into lighter products and coke. Conversion refineries are able to earn part of the heavy/light product price differential. Deep conversion refineries are able to earn the full differential between light and heavy products.

#### 4. The Arthur D. Little Refinery LP Model

##### Model Description

Over the past several years, Arthur D. Little has developed large-scale computer models for simulating the major world refining

centers. In such models a specified product demand pattern is met by a specified crude slate in an optimized refinery operation. An analysis of model outputs offers valuable insight into crude and refined product values with respect to the stated cost of a reference crude oil. In effect, the model continuously answers the question: "What will it cost to produce an additional barrel of Product X?" and "What would an additional barrel of crude oil Y be worth relative to the reference crude oil and the other crude oils in the crude oil slate?"

A simplified refinery flow sheet shown in Figure A.9 represents one of the models. This particular one is of a U.S. West Coast cluster model and was used in a study of the cost of lead phase-down and sulfur content reduction of gasolines for the Environmental Protection Agency (EPA-450/3-76-016 a and b). This particular model was not used in the current study which was based on confidential, refinery specific models.

The main blocks of the refinery processing scheme can be broken down into: (1) naptha, (b) gas oil, and (c) residual. The full-range ( $C_5$  - 375° F) untreated naphtha can be sold directly. Otherwise, the naphtha is split into several fractions for blending or further processing. The light (200-340) and heavy (340-375) naphthas can each be hydrotreated. Each hydrotreated naphtha can be routed to a catalytic reformer with the option of running at three different octane severities. The model chooses the optimum severity or it can bypass some naptha into finished product blending.

The gas oil processing scheme is less complex than the naptha. The full-range 375-650° F fraction can be split into a kerosene fraction and heavy gas-oil fraction, and each stream can be subsequently hydrotreated.

The residual fraction (atmospheric bottoms) can be directly blended to residual fuel oil or desulfurized before blending if from a sour crude origin. It can also be fed to a vacuum distillation unit; the vacuum overhead stream can then be hydrotreated for fuel-oil blending or fed to a FCC or HCC for conversion into lighter products. The model is allowed the option of choosing between two catalytic cracking conversion levels or several grades of vacuum gas oil feed. The propylene-butlenes from catalytic cracking can be fed to an alkylation unit or to a polymerization unit to make gasoline blending stocks. Vacuum bottoms can be routed to a coker to reduce the production of fuel oil and to produce some lighter products and coke. The coker naphtha can be hydrotreated and the heavy fraction reformed. The coker gas oil can also be hydrotreated and the heavy fraction cracked.

Additional processes in the model not shown on this refinery flow sheet include a hydrogen plant. (If the volume of hydrogen required for treating exceeds that supplied from catalytic reforming, then

hydrogen must be manufactured either from refinery gas, naphtha and/or residual fractions.) The refinery is usually required to generate its own steam and power, although these can be variable options. A sulfur plant is provided which converts hydrogen sulfide into elemental sulfur.

ADL has accumulated industry data for each processing unit for each crude oil. This includes yields and key properties of the products from that particular process, capital costs, and operating costs divided into the following seven categories: refinery fuel consumption, steam, water, electric power, catalysts and chemicals, operating labor, and maintenance. The capital and operating costs for each refinery process unit are based on modern units of the size consistent with each selected refinery process unit capacity.

The costs of offsites for crude handling and product blending and storage is included and varies with crude distillation capacity. An internal refinery fuel balance is maintained (including fuel needed for steam generation, power generation, etc.) with a maximum sulfur content specification.

#### Economic Basis

The data supplied to the model for the computer runs consists of:

- o Product demands and specifications;
- o Crude supply; and
- o Refinery processing options for each crude.

Product demands were fixed volumes which must be met in this study. However, we can allow product volumes to optimize at specified netbacks, sometimes limiting minimum or maximum levels.

The basic assumption underlying our use of fixed product demands is that the total market for petroleum products in a refining center is relatively inelastic to changes in product prices. This is most true for products such as gasoline and jet fuel which have no competitive supply source. Heating oil and residual fuel have had inter-fuel competition from natural gas and coal in the past. One result of this is that residual fuel has been sold below its investment cost value. If we expect this condition to continue, we can remove the fixed volume restriction for residual fuel oil and allow it to seek its own optimum production level at an inter-fuel competitive price structure.

In a multi-crude system, crude slate is usually specified as a fixed supply for all crudes except a marginal crude<sup>2</sup> in which must be allowed to vary in order to meet a fixed product slate because it is not known in advance the exact volume of crude oil that will be required due to gains/losses from refinery processes and own fuel

---

2

Alaskan North Slope crude is the marginal California crude.

consumption. The volume of the marginal crude consumed will vary somewhat from run to run. A delivered price is assigned to this reference crude, and all other crude and product values are determined relative to the reference crude oil price chosen.

For each refinery process in the model, the capital cost is supplied plus several categories of operating costs. The capital cost is converted to a daily cost basis via a capital recovery factor. The capital charge provides for depreciation, income tax, property tax and insurance, and profit. Other cost categories can be selectively included or excluded so that the model can represent operations under variable cost, cash cost or fully built up cost conditions.

The linear programming algorithm will optimize the refinery processing scheme at minimum cost to meet the required product demands and product specifications from the crude slate provided. It is assumed that complete interchange of intermediate streams from all crudes is possible.

The most useful outputs from the linear programming runs are the optimum refined process schemes chosen for each crude oil and the shadow prices for the refined products and crude oils. These shadow prices indicate the internal refinery values for each respective product and each crude oil and indicate the minimum long-term selling price that a particular product requires in order to justify capital expenditures for its manufacture or the maximum long-term purchase price for each crude oil. The product values (sometimes called investment cost values) are often used to major oil companies as transfer values when transferring products from refining to marketing divisions and also from refinery to petrochemical divisions.

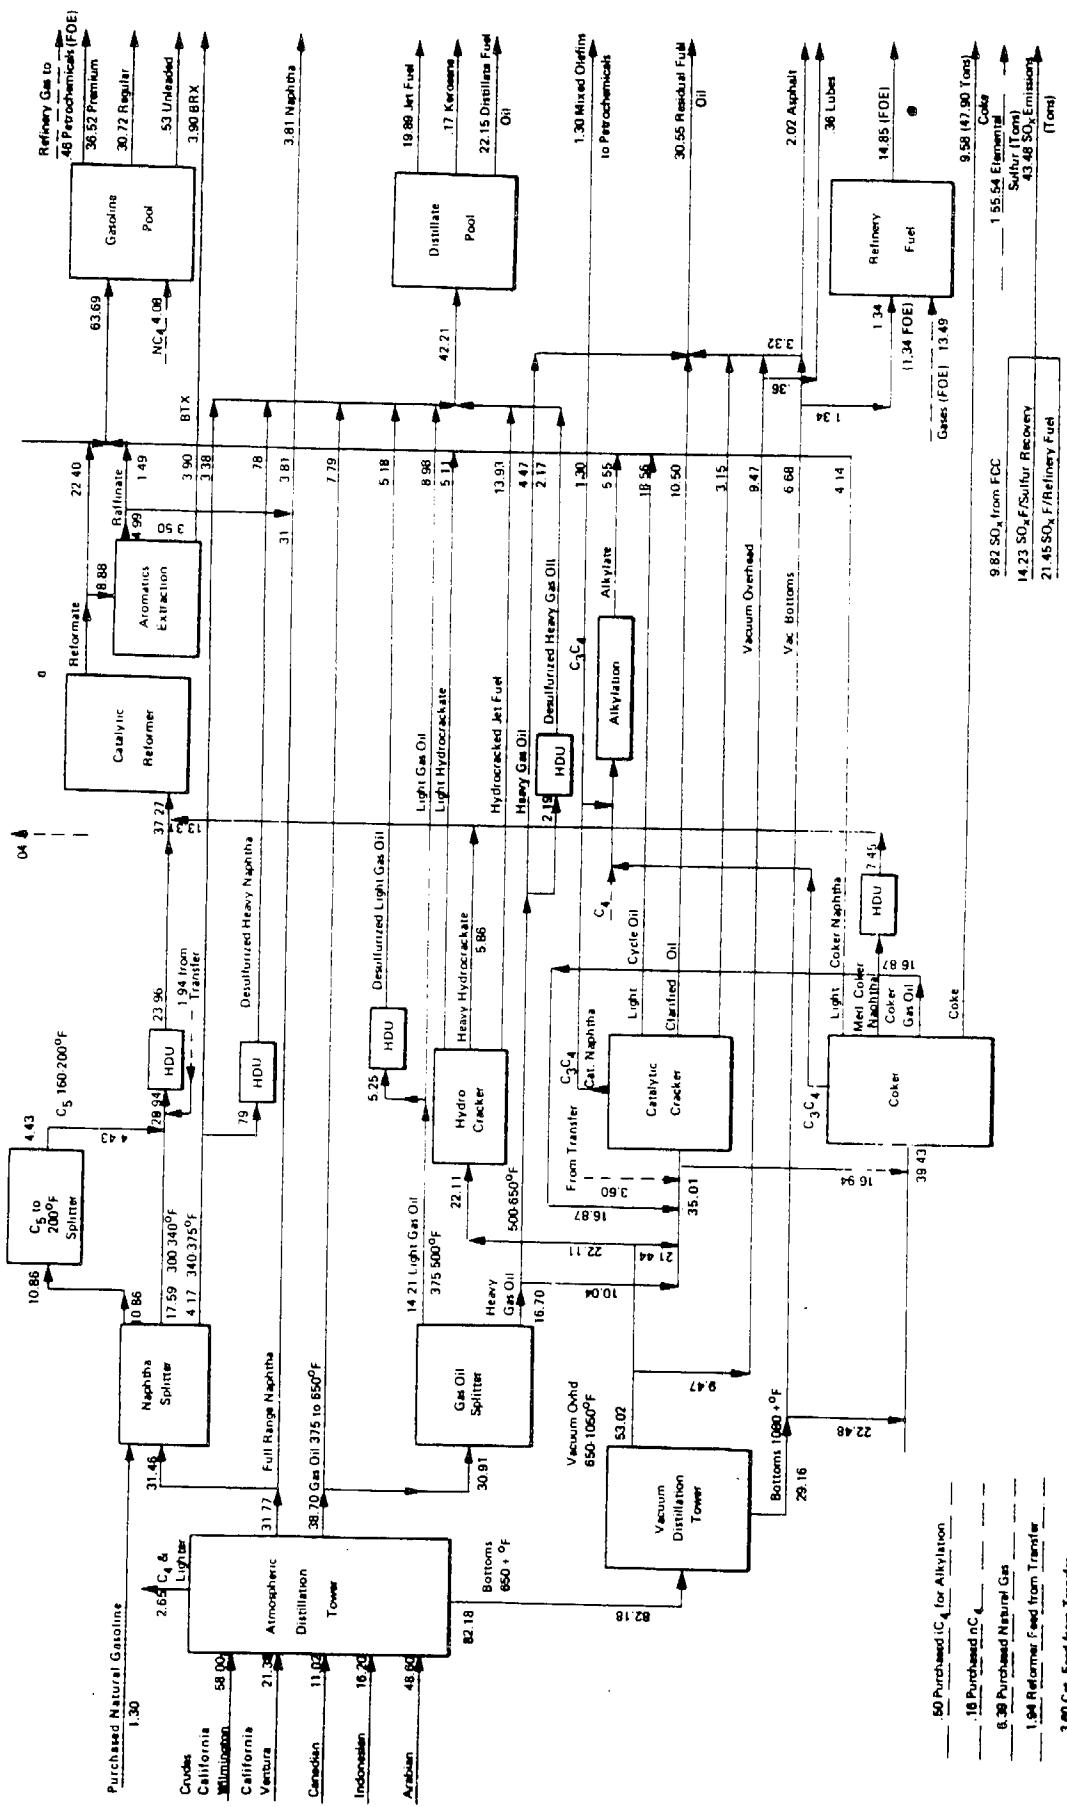

The relative crude values simulate the internal crude oil values assigned by large, integrated oil companies which have the flexibility to reallocate crudes among various refineries to optimize its operations in a large geographic region.

In parametric evaluations, we systematically vary certain key uncertainties in our input data (such as product demand levels, specifications, operating costs, crude supply patterns, etc.) to test the flexibility of model outputs to these changes. A parametric evaluation consists of an alternate unique LP solution for each variation in input data. We can thus evaluate on a quantitative basis the extent to which a variation in a particular input forecast will affect the conclusions, in particular, gasoline and diesel quality in this analysis.

It is important to emphasize that the crude and product values generated by the refinery simulation model are costs and not prices. Market constraints can and do limit the extent to which a refinery can recover the costs allocated to each product in the model. However, the model does show when additional costs are incurred in making more

of a particular product. It indicates a lower market value for high-sulfur crude oils and a higher market value for low-sulfur crude oils as the demand for low-sulfur products increases. The crude oil values are not prices but replacement values; that is, the value at which a refiner would replace a barrel of the reference crude with the barrel of another crude oil. A high replacement value for a given crude oil means that the refinery can reduce refining costs by substituting this crude oil for a low replacement value crude oil.

B. CHARACTERIZATION OF 1986 CALIFORNIA REFINERIES

1986 CA Refinery Groups

Group 1: Topping: (1)

Conoco	Santa Maria
Edgington	Long Beach
Witco Chemical (Golden Bear)	Oildale
MacMillan	Signal Hill
Oxnard	Oxnard
San Joaquin RFG	Bakersfield
Huntway RFG	Benicia
Huntway RFG	Wilmington
Gibson Oil	Bakersfield

Subtotal Operating: 9

Shutdown:

Demenno-Kerdoon	Compton
ECO	Signal Hill
Gasco	Anchor
Lunday Thagard	South Gate
Western Oil & RFG (Marlex)	Long Beach
West Coast Oil	Bakersfield
Golden Eagle	Carson

Subtotal Shutdown: 7

Total Refineries in Group: 16

Group 2: Hydroskimming: (1)

Beacon	Hanford
Kern County	Bakersfield
Newhall RFG	Newhall
Paramount (old Conoco)	Paramount
Sunland	Bakersfield

Subtotal Operating: 5

Shutdown:

Chevron	Bakersfield
USA Petrochem	Ventura

Subtotal Shutdown: 2

Total Refineries in Group: 7

1986 CA Refinery Groups (Continued)

Group 3: Complex-Without Coking:

Chevron	Richmond
Fletcher	Carson
Golden West	Santa Fe Spr.
Pacific RFG	Hercules
Texaco	Bakersfield
Unocal <sup>(2)</sup>	Los Angeles

Total Refineries in Group: 6

\* Included in complex category due to purchase of shutdown Tosco refinery during 1986.

Group 4: Complex-With Coking/FCC:<sup>(2)</sup>

Champlin	Wilmington
Shell	Wilmington

Total Refineries in Group: 2

Group 5: Complex-With Coking/FCC/HCC at 0.05%S Diesel:<sup>(2)</sup>

ARCO	Carson
Chevron	El Segundo
Mobil	Torrance
Texaco	Wilmington

Subtotal operating: 4

Shutdown:

Powerine	Santa Fe Spr.
----------	---------------

Total Refineries in Group: 5

Group 6: Complex-With Coking/FCC/HCC at ASTM Diesel:

Exxon	Benicia
Shell	Martinez
Tosco	Martinez
Unocal	Rodeo & Santa Maria

Total Refineries in Group: 4

1986 CA Refinery Groups (Continued)

Summary

	<u>Operating</u>	<u>Shutdown</u>	<u>Total</u>
Current ASTM Diesel	23	9	32
Currently at 0.05%S Diesel	7	1	8
Total	<u>30</u>	<u>10</u>	<u>40</u>

- (1) Refineries currently producing ASTM diesel (< 0.5%S)  
(2) Large refineries in the SCAMD and Ventura Co. currently at maximum 0.05%S diesel.

C. REFINERY SURVEY LETTERS

AUGUST 14, 1987

DEAR MR. :

SUBJECT: SURVEY OF CALIFORNIA REFINERIES: HISTORIC OPERATING DATA AND FUTURE PLANS.

THE AIR RESOURCES BOARD HAS CONTRACTED WITH ARTHUR D. LITTLE, INC. (ADL) TO ANALYZE THE "COSTS OF REDUCING AROMATICS AND SULFUR LEVELS IN MOTOR VEHICLE FUELS". THIS STUDY WILL EXAMINE THE COST IMPACT ON THE CALIFORNIA REFINING INDUSTRY TO REDUCE AROMATICS AND SULFUR LEVELS IN DIESEL AND AROMATICS IN GASOLINE MOTOR VEHICLE FUELS.

THE APPROACH ADL WILL TAKE IN DOING THIS ASSIGNMENT IS TO SIMULATE FIVE INDIVIDUAL CALIFORNIA REFINERIES USING LP MODELLING. THE REFINERIES HAVE BEEN CHOSEN TO REPRESENT CALIFORNIA REFINERY PROCESSING CAPABILITY IN THE REFINING INDUSTRY IN FIVE CONFIGURATION CLASSIFICATIONS. THE INDIVIDUAL REFINERY MODELS WILL BE VALIDATED AGAINST ACTUAL REFINERY OPERATION IN TERMS OF CONFIGURATION, CAPACITY, PROCESSING FLEXIBILITY, INPUTS, PRODUCT OUTPUTS, AND OPERATING COSTS. THE RESULTS FROM THE INDIVIDUAL REFINERY MODELS WILL BE SCALED UP FOR EACH OF THE CONFIGURATION GROUPS TO REPRESENT OVERALL CALIFORNIA REFINERY OPERATION. IN ORDER TO ENSURE THAT THIS STUDY IS BASED ON THE BEST AVAILABLE INFORMATION AND TO CALIBRATE THE ANALYSIS, WE ARE CONDUCTING A SURVEY OF CALIFORNIA REFINERY HISTORIC OPERATING DATA AND FUTURE PLANS.

YOUR REFINERY AT HAS BEEN SELECTED AS REPRESENTATIVE OF A NUMBER OF REFINERIES IN YOUR CONFIGURATION TYPE. THE DETAILED DATA REQUESTED IN THE ATTACHED QUESTIONNAIRE WILL ENABLE ADL TO CALIBRATE THEIR MODEL FOR REFINERIES OF YOUR CONFIGURATION TYPE FOR 1986 OPERATION.

WE REQUEST THAT THE SURVEY INFORMATION BE FORWARDED TO ADL BY SEPTEMBER 18, 1987. PLEASE ADDRESS YOUR RESPONSE AS FOLLOWS:

Ms. KATHLEEN M. McCARTHY  
ARTHUR D. LITTLE, INC.  
ACORN PARK, MD-315  
CAMBRIDGE, MA. 02140

AUGUST 14, 1987 PAGE 2

MR. ROBERT BIMAT, JR.  
VICE PRESIDENT REFINING  
SUNLAND REFINING COMPANY

PURSUANT TO THE PROVISIONS OF THE PUBLIC RECORDS ACT (GOVERNMENT CODE SECTIONS 6250 ET SEQ.) AND SECTION 91010, TITLE 17, CALIFORNIA ADMINISTRATIVE CODE, THE INFORMATION YOU PROVIDE WILL BE A PUBLIC RECORD AND SUBJECT TO PUBLIC DISCLOSURE, EXCEPT FOR TRADE SECRETS WHICH ARE NOT EMISSION DATA OR OTHER INFORMATION WHICH IS EXEMPT FROM DISCLOSURE OR THE DISCLOSURE OF WHICH IS PROHIBITED BY LAW. THE INFORMATION MAY ALSO BE RELEASED TO THE ENVIRONMENTAL PROTECTION AGENCY, WHICH PROTECTS TRADE SECRETS AND OTHER CONFIDENTIAL INFORMATION IN ACCORDANCE WITH FEDERAL LAW.

INFORMATION CLAIMED TO BE TRADE SECRET OR OTHERWISE EXEMPT FROM DISCLOSURE MAY BE IDENTIFIED AS CONFIDENTIAL IN ACCORDANCE WITH SECTION 91011, TITLE 17, CALIFORNIA ADMINISTRATIVE CODE, WHICH REQUIRES THAT THE CLAIM OF CONFIDENTIALITY BE ACCCOMPANIED BY AN ADEQUATE JUSTIFICATION. THE JUSTIFICATION SHOULD BE AS DETAILED AS POSSIBLE WITHOUT DISCLOSING THE TRADE SECRET OR OTHER CONFIDENTIAL INFORMATION.

THE INFORMATION TO BE COLLECTED BY THIS SURVEY IS AN IMPORTANT ELEMENT IN OUR INVESTIGATION OF THE EFFECTS OF CHANGES TO DIESEL FUEL SPECIFICATIONS. YOUR PROMPT RESPONSE WILL BE GREATLY APPRECIATED. IF YOU HAVE ANY QUESTIONS, PLEASE CALL ROBERT GRANT, RESEARCH CONTRACT MANAGER, AT (916) 323-5774. TECHNICAL QUESTIONS REGARDING THE SURVEY SHOULD BE MADE TO EITHER KATHLEEN M. McCARTHY OR JOHN FELTON AT (617) 864-5770.

THANK YOU FOR YOUR PARTICIPATION.

SINCERELY YOURS,

---

JOHN HOLMES, PH.D.  
CHIEF, RESEARCH DIVISION

## Refinery Questionnaire I

### I. Refinery Material Balance and Fuel Use

Please provide the information as indicated on Table 1 attached for the year 1986.

### II. Process Capability

Please provide 1986 process capability for the processes listed below. In addition, please provide additions to process capability by 1990 based on your current plans under current EPA regulations and ARB regulations.

For all process units provide capacity in MB/SD, MB/CD and 1986 utilization in MB/CD. In addition, please provide the additional process specific data shown below. Please provide separate data for multiple process units of the same type where applicable.

#### 1. Atmospheric Distillation

- TBP cuts on products

#### 2. Vacuum Distillation

- TBP cuts on products

#### 3. Catalytic Reforming

- typical over point and end point of feed
- catalyst regeneration (semi-regen, cyclic, continuous)
- average quality of feedstock (N + 2A)
- average severity (RONC) and hydrogen production (MSCF/B)
- maximum severity (RONC) and hydrogen production (MSCF/B)
- operating pressure

#### 4. Isomerization

- once through or recycle
- feedstock
  - - C<sub>4</sub>
  - - plant C<sub>5</sub>/C<sub>6</sub>
  - - purchased natural gasoline

#### 5. Naphtha Hydrotreating

- feedstock (SRN, Coker Naphtha, Hydrocracker Naphtha etc., by vol %)
- sulfur in (wt%) and sulfur out (wt%)
- hydrogen consumption: MSCF/B ..

#### 6. Kerosine Hydrotreating

- sulfur in (wt%) and sulfur out (wt%)
- aromatics in (wt%) and aromatics out (wt%)

- hydrogen consumption: MSCF/B
- number of stages
- maximum sulfur removal and associated H<sub>2</sub> consumption
- operating pressure
- operating temperature
- disposition of liquid product

7. Distillate Hydrotreating

- feedstock (S.R., Coker, FCC LCGO etc.)
- sulfur in (wt%) and sulfur out (wt%)
- aromatics in (vol%) and aromatics out (vol%)
- cetane no. in and cetane no. out
- hydrogen consumption: MSCF/B
- number of stages
- maximum sulfur removal and associated H<sub>2</sub> consumption
- operating pressure
- operating temperature
- disposition of liquid product

8. Heavy Gas Oil (Vacuum G.O.) Hydrotreating

- feedstocks
- sulfur in (wt%) and sulfur out (wt%)
- aromatics in (vol%) and aromatics out (vol%)
- hydrogen consumption: MSCF/B
- number of stages
- maximum sulfur removal and associated H<sub>2</sub> consumption
- operating pressure
- operating temperature
- disposition of liquid product

9. Residual Hydrotreating

- feedstocks
- sulfur in wt% and sulfur out wt%
- aromatics in (vol%) and aromatics out (vol%)
- hydrogen consumption: MSCF/B
- number of stages
- maximum sulfur removal and associated H<sub>2</sub> consumption
- operating pressure
- operating temperature
- disposition of liquid product

10. FCC

- conversion: vol%
- yield (olefins, gasoline, LCCO, HCCO) vol%
- feedstock(s) (VGO, Coker GO, Long resid, etc, vol%)
- feedstock(s) quality (Aniline point, wt% S)

11. Alkylation/Polymerization

- type (HF, H<sub>2</sub>SO<sub>4</sub>, Cat Poly, Dimersol)
- feedstock (C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub>, vol%)

12. Catalytic Hydrocracking

- feedstock(s) (Distillate, VGO, Coker GO, LCO, etc., vol%)
- hydrogen consumptions (MSCF/B)
- operating pressure: psig
- number of stages
- yield (gasoline, kerosine, distillate vol%)
- maximum severity yield and hydrogen consumption

13. Thermal Processing

- type of unit (i.e., visbreaker, delayed coker, etc.)
- feedstocks (long resid, short resid, etc. vol%)

14. Aromatic Extraction

- B, T, X (vol%)

15. Hydrodealkylation

16. MTBE

17. Hydrogen Generation/Purification

- process type (steam reforming, partial oxidation, purification)
- capacity (MSCF/B pure H<sub>2</sub>)
- feedstock(s) (still gas, natural gas, LPG, naphtha, plant H<sub>2</sub>, etc.)
- production capability with alternative feedstocks
- current refinery hydrogen balance surplus (deficit) MMSCF/D

18. Solvent Deasphalting

- solvent type
- DAO yield vol%
- DAO quality (Aniline point, wt% S)

19. Sulfur Recovery

- number and capacity of units
- sulfur recovery (TN/D)
- percent sulfur recovery
- number of units which are redundant but are required by EPA

III. Product Blending

1. Gasoline Blending

Please provide the following data for all gasoline components blended to your 1986 gasoline pool. Provide breakdown by gasoline grade, if possible.

<u>COMPONENT</u>	<u>1986</u> MB/D	<u>RVP</u> psi	<u>(R+M)/2</u> Clear	<u>TOTAL</u> VOL %	<u>BZ</u> <sup>1</sup> VOL %	<u>TOLUENE</u> <sup>1</sup> VOL %	<u>XYLENE</u> <sup>1</sup> VOL %	<u>C<sub>9</sub>+<sup>1</sup></u> <u>AROMATICS</u> VOL %

Total Distillate							

- (1) Total aromatics most important. Provide levels of polynuclear aromatics (PNA), nitrated PNA and test method, if possible.
- (2) Provide cetane index if cetane number is not available.

#### IV. Product Specifications

Our analysis will be based on current California Product Specifications shown on Table 2. Those specifications that will be controlled in our LP Modelling Analysis are indicated by an asterisk. Please indicate any differences in current product specifications (especially gasoline and diesel) for your refinery. Our study will analyze the impact of reducing gasoline aromatics levels, diesel aromatics levels and diesel sulfur content (except for large refineries in the SCAMD and Ventura County which are currently at .05 wt%S).

#### V. Future Operations

Our analysis will be based on CEC forecasts of crude oil supply and refined product demand for 1990 and 1995.

As a guideline for our analysis, please provide any planned changes for 1990 and 1995 in your:

- Crude slate
- Product slate
- Other feedstocks
- Process modifications or additions

#### VI. Refinery Operating Costs

Please provide the following refinery operating costs for 1986:

	<u>000\$</u>	<u>\$/B Crude</u>
Variable costs		
- Catalyst and chemicals		
- Electric power		
- "Other" variable costs		
- Purchased refinery fuel		
- Subtotal variable costs		
Fixed costs		
- Contract maintenance <sup>1</sup>		
- Maintenance materials <sup>1</sup>		
- Maintenance manpower <sup>1</sup>		
- Operations and administrative manpower <sup>1</sup>		
- Tax, insurance and other		
- Subtotal fixed costs		

#### Total Cash Costs

(1) Include number of employees/contract laborers by category.

VII. Previous Survey Submissions

Under the conditions of secrecy as outlined in our cover letter, we would like access to your submissions to the following previous surveys.

1. Submission to National Petroleum Council for October 1986 U.S. Petroleum Refining Report.
2. Submission to CARB for October 1984 Diesel Fuel Modification Study.
3. Submission to CARB for May 1986 Benzene Control Plan.
4. Submission to NPRA for 1986 Diesel Fuels Survey.
5. DOE Monthly Refinery Reports for 1986 EIA-810.

VIII. Refinery Contact

Please provide the name of a day-to-day contact for questions regarding your submission.

AUGUST 14, 1987

DEAR MR.

SUBJECT: SURVEY OF CALIFORNIA REFINERIES: HISTORIC OPERATING DATA AND FUTURE PLANS.

THE AIR RESOURCES BOARD HAS CONTRACTED WITH ARTHUR D. LITTLE, INC. (ADL) TO ANALYZE THE "COSTS OF REDUCING AROMATICS AND SULFUR LEVELS IN MOTOR VEHICLE FUELS". THIS STUDY WILL EXAMINE THE COST IMPACT ON THE CALIFORNIA REFINING INDUSTRY TO REDUCE AROMATICS AND SULFUR LEVELS IN DIESEL AND AROMATICS IN GASOLINE MOTOR VEHICLE FUELS.

THE APPROACH ADL WILL TAKE IN DOING THIS ASSIGNMENT IS TO SIMULATE FIVE INDIVIDUAL CALIFORNIA REFINERIES USING LP MODELLING. THE REFINERIES HAVE BEEN CHOSEN TO REPRESENT CALIFORNIA REFINERY PROCESSING CAPABILITY IN THE REFINING INDUSTRY IN FIVE CONFIGURATION CLASSIFICATIONS. THE INDIVIDUAL REFINERY MODELS WILL BE VALIDATED AGAINST ACTUAL REFINERY OPERATION IN TERMS OF CONFIGURATION, CAPACITY, PROCESSING FLEXIBILITY, INPUTS, PRODUCT OUTPUTS, AND OPERATING COSTS. THE RESULTS FROM THE INDIVIDUAL REFINERY MODELS WILL BE SCALED UP FOR EACH OF THE CONFIGURATION GROUPS TO REPRESENT OVERALL CALIFORNIA REFINERY OPERATION. IN ORDER TO ENSURE THAT THIS STUDY IS BASED ON THE BEST AVAILABLE INFORMATION AND TO CALIBRATE THE ANALYSIS, WE ARE CONDUCTING A SURVEY OF CALIFORNIA REFINERY HISTORIC OPERATING DATA AND FUTURE PLANS.

THE DATA REQUESTED ON THE ATTACHED SURVEY FORM WILL ENABLE ADL TO SCALE-UP SELECTED REFINERY DATA FOR REFINERIES IN YOUR CONFIGURATION TYPE TO ASSESS THE OVERALL IMPACT ON THE CALIFORNIA REFINING INDUSTRY. IF YOU OPERATE MORE THAN ONE REFINERY IN CALIFORNIA WE REQUEST THAT YOU COMPLETE A SEPARATE SURVEY FOR EACH REFINERY.

WE REQUEST THAT THE SURVEY INFORMATION BE FORWARDED TO ADL BY SEPTEMBER 18, 1987. PLEASE ADDRESS YOUR RESPONSES AS FOLLOWS:

Ms. KATHLEEN M. McCARTHY  
ARTHUR D. LITTLE, INC.  
ACORN PARK, MD-315  
CAMBRIDGE, MA. 02140

AUGUST 14, 1987 PAGE 2

MR. R. P. PAVLETIC  
REFINERY MANAGER  
CHAMPLIN PETROLEUM COMPANY

PURSUANT TO THE PROVISIONS OF THE PUBLIC RECORDS ACT (GOVERNMENT CODE SECTIONS 6250 ET SEQ.) AND SECTION 91010, TITLE 17, CALIFORNIA ADMINISTRATIVE CODE, THE INFORMATION YOU PROVIDE WILL BE A PUBLIC RECORD AND SUBJECT TO PUBLIC DISCLOSURE, EXCEPT FOR TRADE SECRETS WHICH ARE NOT EMISSION DATA OR OTHER INFORMATION WHICH IS EXEMPT FROM DISCLOSURE OR THE DISCLOSURE OF WHICH IS PROHIBITED BY LAW. THE INFORMATION MAY ALSO BE RELEASED TO THE ENVIRONMENTAL PROTECTION AGENCY, WHICH PROTECTS TRADE SECRETS AND OTHER CONFIDENTIAL INFORMATION IN ACCORDANCE WITH FEDERAL LAW.

INFORMATION CLAIMED TO BE TRADE SECRET OR OTHERWISE EXEMPT FROM DISCLOSURE MAY BE IDENTIFIED AS CONFIDENTIAL IN ACCORDANCE WITH SECTION 91011, TITLE 17, CALIFORNIA ADMINISTRATIVE CODE, WHICH REQUIRES THAT THE CLAIM OF CONFIDENTIALITY BE ACCCOMPANIED BY AN ADEQUATE JUSTIFICATION. THE JUSTIFICATION SHOULD BE AS DETAILED AS POSSIBLE WITHOUT DISCLOSING THE TRADE SECRET OR OTHER CONFIDENTIAL INFORMATION.

THE INFORMATION TO BE COLLECTED BY THIS SURVEY IS AN IMPORTANT ELEMENT IN OUR INVESTIGATION OF THE EFFECTS OF CHANGES TO DIESEL FUEL SPECIFICATIONS. YOUR PROMPT RESPONSE WILL BE GREATLY APPRECIATED. IF YOU HAVE ANY QUESTIONS, PLEASE CALL ROBERT GRANT, RESEARCH CONTRACT MANAGER, AT (916) 323-5774. TECHNICAL QUESTIONS REGARDING THE SURVEY SHOULD BE MADE TO EITHER KATHLEEN M. McCARTHY OR JOHN FELTEN AT (617) 864-5770.

THANK YOU FOR YOUR PARTICIPATION.

SINCERELY YOURS,

---

JOHN HOLMES, Ph.D.  
CHIEF, RESEARCH DIVISION

## Refinery Questionnaire II

I. Please provide the information as indicated on Table 1 attached for the year 1986.

### II. Process Capability

Our analysis will be based on January 1, 1987 capacities published in the Oil and Gas Journal and DOE Annual Refinery Surveys, unless you provide alternate data.

Please provide 1986 process capability for the processes listed below. In addition, please provide additions to process capability by 1990 based on your current plans under current EPA regulations and ARB regulations.

#### 1. Catalytic Reforming

- typical over point of feed
- average quality of feedstock (N + 2A)
- average severity (RONC) and hydrogen production (MSCF/B)
- maximum severity (RONC) and hydrogen production (MSCF/B)
- operating pressure

#### 2. Distillate Hydrotreating

- feedstock (S.R., Coker, FCC LCGO etc.)
- sulfur in (wt%) and sulfur out (wt%)
- aromatics in (wt%) and aromatics out (wt%)
- hydrogen consumption: MSCF/B
- number of stages
- maximum sulfur removal and associated H<sub>2</sub> consumption
- operating pressure
- operating temperature
- disposition of liquid product

#### 3. Heavy Gas Oil (Vacuum G.O.) Hydrotreating

- feedstocks
- sulfur in (wt%) and sulfur out (wt%)
- aromatics in (wt%) and aromatics out (wt%)
- hydrogen consumption: MSCF/B
- number of stages
- maximum sulfur removal and associated H<sub>2</sub> consumption
- operating pressure
- operating temperature
- disposition of liquid product

#### 4. FCC

- conversion: vol%
- yield (olefins, gasoline, LCCO, HCCO) vol%
- feedstock(s) (VGO, Coker GO, Long resid, etc, vol%)
- feedstock(s) quality (Aniline point, wt% S)

## 5. Catalytic Hydrocracking

- feedstock(s) (Distillate, VGO, Coker GO, LCO, etc., vol%)
- hydrogen consumptions (MSCF/B)
- operating pressure: psig
- number of stages
- yield (gasoline, kerosine, distillate vol%)
- maximum severity yield and hydrogen consumption

## 6. Thermal Processing

- type of unit (i.e., visbreaker, delayed coker, etc.)
- feedstocks (long resid, short resid, etc. vol%)

## 7. Aromatic Extraction

- B, T, X (vol%)

## 8. Hydrogen Generation/Purification

- process type (steam reforming, partial oxidation, purification)
- capacity (MSCF/B pure H<sub>2</sub>)
- feedstock(s) (still gas, natural gas, LPG, naphtha, plant H<sub>2</sub>, etc.)
- production capability with alternative feedstocks
- current refinery hydrogen balance surplus (deficit) MMSCF/D

## III. Gasoline Blending

Please provide volume percent blended, (R+M)/2 clear and volume percent aromatics content of all gasoline components.

## IV. Diesel Blending

Please provide volume percent blended, wt.% sulfur and volume percent aromatics content of all distillate components blended to diesel and No. 2 fuel. Show diesel and No. 2 fuel as one product if not segregated and indicate the degree of segregation possible.

## V. Future Operations

Our analysis will be based on CEC forecasts of crude oil supply and refined product demand for 1990 and 1995.

As a guideline for our analysis, please provide any planned changes for 1990 and 1995 in your:

- Crude slate
- Product slate
- Other feedstocks
- Process modifications or additions

VI.      Refinery Contact

Please provide the name of contact for questions regarding your submission.

Maintenance: % Process	4.0	4.0	4.0
% Offsites	2.5	2.5	2.5

<sup>1</sup> 1987 USGC location. California = 1.05 x USGC location.  
<sup>2</sup> Typical data. Feedstock quality, product quality and hydrogen consumption are feed specific.

<sup>3</sup> Stage 1 product: 1 ppm Nitrogen

<sup>4</sup> Costs are based on the UOP AH Unibon process extrapolated from commercial processing of straight run distillates. To provide definitive estimates of LCO UOP would need to conduct a pilot plant program followed by some engineering design and estimating work.

MOBIL METHANOL TO OLEFINS PROCESS

Basis: Sized on produce 11,000 B/D distillate on MOGD  
 1987 U.S. Gulf Coast Costs. California = 1.05 x USGC location  
 330 SD/yr operation
